Also known as royal anade or blue anade, it is a natural bird in the Northern Hemisphere. The distribution consists of temperate temperature ranges in North America, Europe, Asia and North Africa. There are sedentary populations on the islands of Hawaii and Laysan. It is a common surface duck and widespread. It is also the most frequent Central America and the Caribbean, including Cuba. He's probably the most famous of all the ducks. It belongs to the anatidae family of the order Anseriformes, the common name in English is Mallard. Characteristics The English duck reaches the length of 50 to 65 cm. Males weigh 0.85 to 1.57 kg and female between 0.75 and 1.32 kg (females sometimes weigh more than males). The wingspan can exceed 90 cm. In this species there is a clear sexual dimorphism. The male has a yellow bill, intensely green head (the texture reminds us of velvet), white collar, chest of some reddish-brown tones, the lower half of the body of light tones and wings with color between brown and white, both colors quite mixed. On the wings there is a purple blue mirror bordering above and below by a white line (during the flight it can be easily identified). The female has a greenish-brown bill, and a body of cryptic brown tones of 3 or 4 different shades. On your face you can see a small list dark that crosses the eye and reaches the beak. It also presents in each wing a purple blue mirror bordering above and below by a white line. In both sexes, the legs are intense orange. In non-bridal season both genera have much duller colors, although they can be differentiated with some ease. The flight of such birds is unmistakable, due to the completely horizontal position of the neck and the rapid wing flap. It builds its nest on the ground, with twigs and feathers, in areas of vegetation on the banks of the waterways where it lives. It is an omnivorous and opportunistic species. Dedada consists of nine to thirteen greenish-gray eggs. Incubation takes 27 to 28 days. The cubs fly for 50 to 60 days. Habitat It is a highly adaptable species that lives without problems in almost all kinds of aquatic environments: lagoons, marshes, slow current rivers, rice fields, areas of salobre water and can even be seen resting in the ocean during the day. It is very common to observe this species in parks and public gardens in many cities and towns. Samples of this species have been observed from sea level to 2000 m altitude, although they most often live in areas between 0 and 400 m above sea level. Food Feeds on both plant material (plants, seeds, fruits, etc.) as well as small fish, invertebrates.
